

OkBuddy CV Editor – Work Experience

First Bullet Input Flow Product Spec

Goals

- **Maximize AI Feature Engagement:** Ensure that every user **experiences the AI assistance at least once** when adding work experience, rather than skipping it. The first bullet point entry for a job is designed to funnel the user into using either the AI “**Tạo nhanh**” wizard or the template “**Dùng mẫu**” option, thereby triggering an “aha” moment with OkBuddy’s AI.
- **Minimal & Focused Initial UI:** Present a clean, focused interface for the first work experience bullet. By hiding the free-text editor initially and showing only two clear choices (AI wizard or templates), the user’s attention is directed to these assistive tools. This reduces distraction and makes the decision to use AI assistance front and center.
- **One-Time Enforcement, Then Flexibility: Force engagement only for the first bullet** of a new Work Experience entry. After the user generates or inserts that first bullet via one of the guided methods, the editor reverts to the normal flexible mode. The user regains full control to add/edit bullets freely from the second bullet onward, having seen the value of the AI on the first one.
- **Onboarding & Guidance:** Provide brief **in-product guidance (tooltips)** to explain the “Tạo nhanh” and “Dùng mẫu” options when the user first encounters them. This educates new users on what these options do (AI-generated content vs. template-based entry) and why they’re useful, increasing the likelihood of engagement.
- **Improved Input UX:** Streamline the bullet editing experience. For all bullet fields (after the first is added), make the **Enter key create a new bullet** (like a list editor) instead of inserting a newline, to speed up multi-bullet entry. Allow **Shift+Enter** for those rare cases where a newline *within* a bullet is needed. Automatically focus new bullet fields when created. This makes the manual editing experience faster and more intuitive once it’s unlocked.

Functional Requirements – First Bullet Guided Flow

1.

Initial State (New Work Experience Entry)

When the user adds a **new Work Experience entry** (i.e. a job position with no description bullets yet), the editor will initialize in a special **guided mode for the first bullet**:

- The usual input fields for **Job Title, Company, Dates, Location** are displayed as normal at the top of the entry form. Below that, the **Work Description** section (bullet list) is initially **empty**, with **no text-area or bullet input field shown**.
- In place of the normal bullet input field, the UI shows **two large side-by-side button options** centered in the empty bullet list area: **“Tạo nhanh”** and **“Dùng mẫu.”** These serve as the only entry points for creating the first bullet. The intent is to make it obvious that the user should click one of them to proceed, rather than typing manually.
- The **“Tạo nhanh” (Quick Create)** button will be styled as a primary action (e.g. prominent color or first in order) since it invokes the AI wizard, which we want to encourage. The **“Dùng mẫu” (Use Template)** button is placed next to it as an alternative. Both are prominent and easy to click on any device (desktop or mobile).
- **No standard bullet editor controls are visible** in this state: the **text input area for the bullet is hidden**, and the usual **+ Thêm gạch đầu dòng** (Add bullet point) button is not shown. We also hide the **“Cải thiện với OkBuddy AI”** (Improve with AI) wand icon for now. This ensures the interface is minimal and that the user’s only obvious actions are the two provided options. This design mirrors the approach used in the Summary section, where an empty field shows a **single CTA to generate content** instead of a blank editor . By not showing a blank text box initially, we **prevent the user from bypassing** the AI/template options and **encourage them to click one of the CTAs**.

2.

Pre-First-Bullet Button Behavior

Until the first bullet is created, the two CTA buttons function as follows:

- **“Tạo nhanh” – Launch AI Wizard:** Clicking this button opens the **interactive 3-step AI wizard** (as per the existing OkBuddy design) for generating a work experience bullet . The wizard modal will ask the user a series of questions (e.g. about a key project and its impact) to gather context, then use the LLM to generate a tailored bullet point .
 - The wizard flow remains the same as currently specified: the user is prompted for at least two inputs (accomplishment and result), optionally a responsibility, then clicks “Generate.” A loading indicator appears while the AI writes the bullet .
 - **Upon completion**, the wizard modal closes and the system inserts the generated bullet text into a new bullet entry field under that job . For example, if the user entered “developed a new CRM system” and “improved data accuracy

by 30%” in the wizard, the resulting bullet might read: *“Led development of a new CRM system, improving data accuracy by 30%.”* This text now populates the first bullet field. (It may appear with a brief highlight or other indication that it was AI-generated, as an added touch.)

- After insertion, the **first bullet is now filled** and the editor will transition to the **post-unlock state** (described in section 3 below). At this point, the special CTA buttons will disappear and the standard bullet editing UI will be restored. The user can then review and edit the AI-generated bullet freely. (The generated bullet should be considered a high-quality first draft that the user can tweak as needed .)
- **“Dùng mẫu” – Use Template:** Clicking this button opens a **bullet template selection interface**. This could be a modal or dropdown that presents one or more example bullet structures or sample texts relevant to the user’s role. (We will leverage the existing template library logic already in the product for work experience suggestions.)
 - The user chooses a template from the list of suggestions. For example, a template might be a generic achievement phrased as *“Led [team/task] to [outcome], resulting in [impact].”* . The system then inserts this template text into the first bullet field. Typically, the template will contain placeholder segments (like “[team/task]”) which the user can then click and edit inline with their specific details. **Alternatively**, the template might be a complete example bullet relevant to the user’s job title (if such context is available), which the user can modify as needed.
 - As soon as the template bullet is inserted into the first bullet field, the editor **unlocks into normal mode** (same as if an AI-generated bullet was inserted). The user now has a first bullet written (albeit a template) that they can customize. This fulfills the goal of getting something on the page to overcome the blank slate. (In the backend, using a template is essentially the “fallback scaffolding” approach for users who don’t use the wizard .)
 - After insertion of the template bullet, the special “Tạo nhanh”/“Dùng mẫu” buttons disappear and full editing controls appear, exactly as if an AI bullet had been generated.

No other actions for adding a bullet are enabled while in the pre-first-bullet state – the user must choose either the wizard or a template to proceed. This ensures they receive assistance rather than writing from scratch on the very first bullet. (If they somehow try to bypass this via unusual means, see **Edge Cases** below.)

3.

Post-Unlock State (Normal Editor Resumes)

Once the first bullet point has been added (whether via **Tạo nhanh** or **Dùng mẫu**), the Work Experience description section returns to the **standard editing mode**:

- The **bullet text input field** for the first bullet is now visible (populated with the content that was generated or templated). The user can click into this field and edit the text freely, as they would with any normal resume bullet. They now have full control to adjust wording, add details, or delete content. The AI-suggested/template text is meant to be a starting point that the user can refine, which addresses the blank-page problem while keeping the user in control .
- The “**+ Thêm gạch đầu dòng**” (**Add bullet point**) **button** appears below the first bullet. The user can click this to create additional bullet entries for that job, identical to the usual behavior. From this point onward, the user is free to add as many bullets as needed manually.
- The “**Cải thiện với OkBuddy AI**” button (Improve with AI) now becomes visible next to the bullet (and for any new bullets going forward). This is the wand icon or improvement CTA that allows one-click AI enhancement of a bullet’s text. It should now be shown for the first bullet (and subsequent ones) because we have content present. (Per our standard design, the Improve AI CTA is available for any bullet point that has text , whether user-written or AI-generated). The user can use this to refine the generated or template text further – for example, to tighten the phrasing or add more impact – with a single click.
- The special first-bullet prompt buttons (“Tạo nhanh”/“Dùng mẫu”) are **removed from the UI** at this stage. They **will not reappear** for this job entry now that it has at least one bullet. The interface now looks and behaves just like the normal editor: a list of bullet fields. (In other words, we only show the two big buttons on an initially empty entry; once filled, we revert to the normal list UI.) This approach is consistent with how we handle other sections like Summary – e.g., once content exists, the “Generate” CTA is replaced by the standard edit/improve controls .
- **Important:** If the user deletes the generated/template bullet after this point (making the job have zero bullets again), **we do NOT revert** to showing the “Tạo nhanh/Dùng mẫu” overlay. The editor remains in the normal state (an empty bullet text field with the standard controls visible). We consider the guided flow “experienced” for that entry; the user chose to remove the content, so we assume they may prefer to write manually at that point. Reverting to the forced wizard could be jarring. (They could still manually invoke the wizard via other means if desired – see Additional Notes.) The key is that the special prompt is shown **only on the very first insertion** for a new entry, and not repeatedly every time the field goes empty.

4.

Bullet Input Behavior Enhancements

To improve the overall UX of editing bullets (for the first bullet after it's added, and all subsequent ones), we are introducing some **keyboard behavior changes** in the bullet list component:

- **Enter to Add New Bullet:** Pressing the **Enter key** while the cursor is in an existing bullet's text field will now **create a new bullet below** (just as if the user clicked the “+ Thêm gạch đầu dòng” button). Instead of inserting a newline character in the same bullet, Enter will function as a shortcut to move to the next bullet. This makes writing multiple bullets faster and more natural (the user can keep typing bullets in sequence without leaving the keyboard). Many users expect this behavior from list editors in other applications.
- **Shift+Enter for New Line:** If the user really needs a newline *within* a bullet (an uncommon scenario, since resume bullet points are usually one-liners), they can press **Shift + Enter**. This key combo will insert a line break in the same bullet text, allowing a second line in the bullet. We will support this for completeness, but by default encourage single-line bullets. A small tooltip or placeholder text can hint this behavior (e.g., “Enter: new bullet; Shift+Enter: line break”).
- **Auto-Focus on New Bullet:** When a new bullet is created (whether by pressing Enter or by clicking the add button), the cursor will **automatically focus** into the new bullet's input field. The newly created bullet field should be scrolled into view if needed and receive keyboard focus, so the user can immediately start typing the next bullet without an extra click. This streamlines the flow of entering multiple bullets.
- These input enhancements apply globally once the bullet editor is in normal mode (i.e. after the first bullet is in place). They will be implemented in the bullet list component so that all Work Experience entries benefit from the improved behavior. (They do **not** affect the initial wizard/template prompt state, since in that state the user isn't typing directly into a bullet field at all.)

5.

Onboarding UX for First-Time Users (Tooltips)

For users who are encountering the Work Experience section for the **first time ever**, we will provide a one-time onboarding hint to explain the two new options:

- When the user enters the Work Experience editor with no existing entries (e.g., the very first time they add a job), we will trigger **brief tooltips or callouts** pointing to the “**Tạo nhanh**” and “**Dùng mẫu**” buttons. For example, a tooltip with an arrow might point at **Tạo nhanh** and say: “*Dùng AI để tạo mô tả công việc nhanh chóng, chuyên nghiệp.*” (Translation: “Use AI to quickly generate a professional job description.”) Meanwhile, another tooltip could point at **Dùng mẫu**: “*Chọn mẫu mô tả sẵn có và điền thông tin của bạn.*” (“Choose a ready-made description template and fill in your details.”). These messages appear in Vietnamese since the UI is Vietnamese, educating the user on what each option does.
- The tooltips should be visually subtle yet noticeable (e.g., small popover bubbles or highlights) and appear only **once** the first time the user is in this flow. The user can dismiss them by clicking an “X” or by clicking the associated button. We want to **avoid overwhelming** the user, so these hints are short and only shown initially. This is similar to providing a one-time hint in the Summary section for first-time users .
- We will use a flag (e.g., in localStorage or the user’s profile data) to remember that the tooltips were shown. After they’ve been displayed once, they will not appear again for that user. Even if the user adds another new Work Experience entry later, we assume they already understand the “Tạo nhanh” vs “Dùng mẫu” choices from the first time. (However, the basic two-button UI will still appear on any new empty entry – just without extra explainers.)
- If the user does not interact and simply dismisses these onboarding tips, the functionality of the buttons is unchanged. The tips are purely educational. Our goal is to increase user awareness and adoption of the AI wizard and templates by making their purpose clear upfront.

Edge Cases & Error Handling

- **Wizard Cancelled/Closed Early:** If the user clicks “**Tạo nhanh**” and launches the wizard but then **exits before finishing** (e.g. closes the modal or skips all questions without generating a bullet), we **do not insert any bullet**. The system will remain in the **pre-first-bullet state**, still showing the “Tạo nhanh” and “Dùng mẫu” buttons . The user can click “Tạo nhanh” again to restart the wizard, or use “Dùng mẫu” instead. In other words, as long as no bullet was actually generated/selected, the first-bullet remains empty and the user is again presented with the two options. This ensures the user is not left stranded with an empty field – they will always be offered either the wizard or templates until something is entered. (Internally, if the wizard was canceled, we may consider re-opening it to the last step or clearing its state – but in either case, the UI

outside the modal stays in the prompt mode.)

- **AI Generation Failure:** If the user does go through the AI wizard and clicks “Generate” but the **LLM fails to return a bullet** (due to a network error, server issue, or any other API failure), the system will handle it gracefully. We will **not insert a blank bullet**. Instead, the user sees an **error message** in context (for example, within the wizard modal or as a notification toast) saying: *“Xin lỗi, OkBuddy AI đang gặp sự cố. Vui lòng thử lại.”* (In English: “Sorry, OkBuddy AI is taking a break. Please try again in a moment.”) . The wizard should offer a **“Thử lại” (Retry)** button or an easy way to re-attempt the generation . Crucially, we will **preserve the user’s inputs** in the wizard so they don’t have to retype their answers when retrying . The user can also opt to cancel out of the wizard if they prefer not to retry, in which case we return to the pre-first-bullet state with the two option buttons still visible.
- **Template Selection Cancelled:** If the user clicks **“Dùng mẫu”** but then closes the template dialog without choosing anything, the result is similar to the above – no bullet is inserted and the interface stays in the initial two-button state. They can reopen the template chooser again via the button or switch to the wizard option. Essentially, until a bullet is actually inserted, the system continues to show the prompt buttons. (If we have only one template option and the user cancels, it’s just no action; if multiple, they simply don’t pick one.) There’s no negative consequence; the user is still being guided.
- **Bypassing the UI (Manual Entry via Dev Tools):** We recognize that a tech-savvy user could theoretically open the browser dev console or manipulate the DOM to **insert text into the first bullet field** even though we’ve hidden it. If, by any unsupported means, text appears in the first bullet without using our buttons, the system will interpret this as the first bullet being filled. In this case, the editor should **immediately unlock to normal mode** (since now a bullet exists). We will **not remove the text** or force the wizard if the user has managed to get content in. The normal controls (add bullet, improve, etc.) should appear so the user can continue editing. However, this scenario is outside normal use; we may log an analytics event to note that a bullet was added without using the provided flow (to track if users are trying to circumvent the system). Since this is an edge case, it won’t affect typical users, but the app should handle it gracefully (no endless lock state).
- **Deleting the Only Bullet (Post-Unlock):** If the user deletes the first bullet *after* it was generated or inserted (making the entry empty again), we will **not revert to the special CTA state**. The reasoning is that the user has already gone through the AI/template flow once for that job and presumably got the value or decided to remove it. At this point, the system will just show an empty bullet text field (since in the normal editor there is always at least one bullet field present, even if empty). The user can now type a bullet manually if they wish. We do **not force the wizard again** as that would likely frustrate the user. (The user can still voluntarily click the “Tạo nhanh” wizard icon on that empty bullet if they want to generate again – see Additional Notes – but it’s no longer mandated.) This

behavior ensures the flow is enforced only once per entry.

- **Missing Job Title/Details:** In the case where the user starts the wizard without having filled in the **Job Title or Company** for the new Work Experience entry, the AI can still attempt generation, but the result might be overly generic (since it lacks role context) . To improve output quality, we may add a validation: if Job Title is empty when the wizard starts or when “Generate” is clicked, we could prompt the user “*Hãy nhập chức danh công việc trước để AI gợi ý chính xác hơn*” (“Please enter a job title first for better AI suggestions”). This could be done by disabling the “Generate” button with a tooltip reminder, for example . This is a minor edge detail – the primary flow does not require job title to run, but encouraging a filled title will lead to more tailored bullets. Regardless, the user can proceed without it (especially if they want to see generic suggestions), and the wizard will just omit that context if blank.
- **Multi-language Considerations:** This spec assumes the **UI is in Vietnamese** (as shown by labels like “Tạo nhanh”) but the **generated content** will typically be in the resume’s language (often English, if that’s the user’s chosen resume language). If the user’s resume is in Vietnamese, the AI might need to generate Vietnamese content; however, handling multi-language generation is outside the scope of this specific spec. We will default to the current behavior (usually English output unless otherwise configured) . The key point is that all interface elements introduced here are Vietnamese, consistent with the rest of the UI, while the logic described applies universally.
- **Analytics & Metric Tracking:** To measure the impact of this redesign, we should track key events such as: **WizardOpened**, **WizardCompleted**, **TemplateUsed**, and whether the user edited or deleted the AI/template bullet afterward. This will help in evaluating if forcing the first-bullet flow increases user engagement with AI and if it leads to better resume content completion rates. (This is an implementation detail for the product analytics – not visible to the user.)

Additional Notes

- **Scope of This Change:** This new first-bullet guided flow applies **only to the Work Experience sections** (each job entry’s bullet list). Other sections of the CV Editor, such as **Summary, Education, Skills, etc.**, are **not changed** by this spec. (The Summary section already has its own AI generation CTA when empty, which remains as is .) We specifically target Work Experience because it’s a crucial section where users benefit from AI assistance, and the first bullet is the key entry point to demonstrate that value. Each Work Experience entry the user adds will independently enforce the guided first bullet flow (e.g., if a user adds two new jobs, each job’s first bullet will go through this process). The onboarding tooltips, however, only appear on the very first usage overall (not for every job).

- Return of Standard Controls:** After the first bullet is created and the editor switches to normal mode, all regular features of the Work Experience editor are available. This includes the **Improve with AI** on each bullet, manual editing, drag-and-drop reordering of bullets (if supported in the broader editor), etc. The user should feel that after the initial guided step, they have the full flexibility they would expect. The design is meant to be minimally intrusive: *guide once, then get out of the way*. Users who prefer manual editing can simply edit or remove the AI/template text once it's inserted – but at least they gave the assistive tools a try.
- Re-invoking the AI Wizard Later:** Even though the large “Tạo nhanh” button is removed after the first bullet, users can still access the AI wizard for additional bullets if they want. For instance, after adding one bullet, a user might click the “+ Thêm gạch đầu dòng” to add a second bullet, which starts empty – at that point, we can provide a small ✨ **icon or menu option** next to that empty bullet to “**Tạo nhanh bullet khác**” (“Quick-generate another bullet”). In other words, the wizard remains available as a secondary option for any bullet field that is empty, just not in an in-your-face way. (In the original design, the wizard could be launched repeatedly to add multiple bullets, and we will preserve that capability via a subtler UI affordance.) The same goes for templates – the user could have an option to insert a template for a new bullet via a menu. This ensures that AI assistance isn't a one-and-done; the user can continue to leverage it, but only if they choose to. The primary objective, however, is achieved on the first bullet where we required the engagement.
- Onboarding Copy and Dismissal:** The exact wording of the tooltips and their triggers will be refined with UX writing input. We need to ensure the Vietnamese copy is clear and helpful. After one or both tooltips are shown the first time, we won't show them again. If a tooltip is shown and the user clicks the associated action (wizard or template), we consider the onboarding complete for that tip. If they dismiss it without action, we also mark it as seen. The use of localStorage (or a cookie/user flag) to remember this state means even if the session refreshes, the user won't be annoyed by repetitive hints. This aligns with best practices for user education – show hints **once** to teach, then trust the user going forward.
- Collaboration with Existing Improve Feature:** It's worth noting that this first-bullet flow is complementary to the “**Cải thiện với OkBuddy AI**” improvement feature. The improve feature remains available after content exists (as noted above). Users might generate a bullet with the wizard and still click *Improve* to see a refined phrasing, or they might use a template and then use *Improve*. That's fine and encouraged. The spec does not change how improvement works; it only changes how the initial content is first put in. In implementation, we should ensure that once the bullet text is inserted, the improve button is active and uses the same logic as it does for any user-written text.
- Testing and Validation:** This new flow should be tested to ensure that it indeed causes users to engage with AI and that the subsequent experience is smooth. We should verify

that a user who truly wants to skip AI still ends up with at least a template bullet (which they can edit or delete, but at least the system tried). We'll also test the Enter/Shift+Enter behavior thoroughly so that no unexpected newlines or missed bullet creations occur. Edge cases like pasting content or rapidly pressing Enter should be handled (e.g., debouncing the creation of bullets on Enter key). Additionally, user feedback on this flow will be monitored; if users find it too restrictive, we may need to fine-tune the balance between forcing a try and allowing manual input. The aim, however, is to make the AI introduction as seamless as possible – we give help *before* the user even starts typing, rather than after they struggle.

By implementing this **redesigned first-bullet input flow**, we expect more users to discover and trust OkBuddy's AI assistance early in the resume-building process. It ensures every user gets a taste of AI-powered help (or at least a pre-written template) for their work experience, which can inspire them to complete their resume with higher quality content and less frustration. This spec provides the detailed blueprint to achieve that, while still preserving user control and a familiar editing experience after the initial guided step.
